15

16 **Abstract**

17 **Objectives:** An elevated peripheral blood eosinophil (PBE) count during acute exacerbation
18 of chronic obstructive pulmonary disease (AECOPD) is a potential predictor of treatment
19 responsiveness and future exacerbation risk. This study aimed to evaluate the prevalence and
20 clinical significance of elevated PBE counts in hospitalized patients with AECOPD in Oman.

21 **Methods:** This single-center retrospective study included all patients with AECOPD who
22 were admitted to Sultan Qaboos University Hospital between January 2017 and July 2019.
23 The patients were classified as having eosinophilic or noneosinophilic AECOPD based on
24 blood eosinophil counts. An elevated eosinophil count was defined as a blood eosinophil
25 count $> 0.3 \times 10^9$ cells/L on admission. The length of hospital stay, use of oral and inhaled
26 steroids, number of readmissions in a year, and use of mechanical ventilation on admission
27 were compared between the eosinophilic and non-eosinophilic AECOPD groups. **Results:** Of
28 the 102 patients included in the study, 42.2% had eosinophilic AECOPD. The eosinophilic
29 AECOPD group had a reduced length of hospital stay ($P = 0.02$) but an increased risk of
30 readmission in a year ($P = 0.04$). Most patients in both the groups were treated with inhaled
31 and oral steroids. The need for mechanical ventilation did not differ between the groups.

32 **Conclusion:** Eosinophilia is highly prevalent in patients with AECOPD and is associated
33 with a reduced length of hospital stay but an increased risk of readmission in a year. It can be

34 used as a surrogate marker to predict the health outcomes of patients with AECOPD and
35 select treatment options.

36 **Keywords:** Chronic Obstructive Pulmonary disease (COPD); Eosinophils; Steroids; length of
37 stay; hospital readmission.

38

39 **Advances in Knowledge**

- 40 • Eosinophilia is highly prevalent in patients with acute exacerbation of COPD.
- 41 • Eosinophilic exacerbation of COPD is associated with a reduced length of hospital stay
42 but an increased risk of readmission in a year.

43

44 **Application to Patient Care**

- 45 • Peripheral blood eosinophil count can be used as a surrogate marker to predict the
46 treatment response.
- 47 • Peripheral blood eosinophil count can be used to guide the treatment choices for patients
48 with COPD.

49

50 **Introduction**

51 Chronic obstructive pulmonary disease (COPD) is characterized by irreversible airflow
52 limitation. Patients with COPD suffer from exacerbation, reduced quality of life, and
53 increased morbidity and mortality.¹⁻³

54

55 Acute exacerbation of chronic obstructive pulmonary disease (AECOPD) is mainly
56 associated with neutrophilic inflammation; however, predominant eosinophilic airway
57 inflammation has been reported in a subset of patients with COPD.⁴⁻⁶ Up to 40% of patients
58 with COPD have an eosinophilic phenotype of COPD, defined as peripheral blood eosinophil
59 (PBE) counts $\geq 2\%$.⁴ Several studies have shown that patients with elevated PBE counts are
60 at an increased risk of frequent exacerbations but show a good response to steroid therapy.^{1,4}
61 Evidence suggests that circulating eosinophils can be recruited to the lungs and can increase
62 inflammation by the actions of cytokines, immunoregulatory cells, and other
63 proinflammatory mediators.⁷ Accordingly, PBE count has been suggested to be useful as a
64 surrogate marker to direct the use of oral steroid therapy in patients with AECOPD and as a
65 predictor of future exacerbation and disease stability.⁶ The data assessing the role of PBE on
66 mortality outcome are inconsistent.^{8,9} Overall, the role of PBEs in the clinical manifestation

67 of COPD remains highly debatable.^{10,11} No prior study has been conducted in the Middle
68 East to assess the prevalence and clinical significance of eosinophilia during AECOPD. The
69 present study aimed to evaluate the prevalence and clinical significance of elevated PBE
70 counts in hospitalized patients with AECOPD.

71

72 **Methods**

73 This retrospective cohort study was conducted at Sultan Qaboos University Hospital (SQUH),
74 a 500-bed multi-specialty tertiary hospital that provides health care for Muscat and Al-
75 Batinah governorates' residents. It is also considered a major referral center for many
76 specialties that provide high-quality care for patients referred from the entire country of
77 Oman.¹²

78

79 All patients with AECOPD admitted to SQUH between January 2017, and July 2019 were
80 included in the study. We have used the Global Initiative for Chronic Obstructive Lung
81 Disease (GOLD) criteria to ascertain COPD diagnosis for all included patients. In addition,
82 we have included the most recent lung function test before the index hospitalization when
83 there is more than one lung function test. Data were collected from electronic patient records
84 using a standardized electronic data collection sheet. The patients were classified as having
85 eosinophilic or non-eosinophilic AECOPD based on their blood eosinophil counts. An
86 elevated eosinophil count was defined as a blood eosinophil count greater than 0.3×10^9
87 cells/L at the time of admission. In addition, the length of hospital stay, use of oral and
88 inhaled steroids, number of readmissions in a year, and use of mechanical ventilation on
89 admission were compared between the eosinophilic and non-eosinophilic AECOPD groups.

90

91 Categorical variables were reported as numbers and percentages, while continuous variables
92 were expressed as means \pm standard deviations (SDs) for normally distributed data and as
93 medians and interquartile ranges (IQRs) for non-normally distributed data. Continuous
94 variables between the groups were compared using Student's t-test for normally distributed
95 data and Wilcoxon's rank-sum test for non-normally distributed data. Fisher's exact test was
96 used to assess the association between categorical variables (given the small sample size). A
97 2-sided p-value < 0.05 was considered statistically significant. Statistical calculations were
98 performed using the Stata v. 16.1 software package (StataCorp LLC, USA).

99

100 The study was approved by the Medical Research Ethics Committee of the College of

101 Medicine and Health Sciences of Sultan Qaboos University.

102

103 **Results**

104 A search of the hospital database revealed 128 patients with AECOPD who were hospitalized
105 during the study period. Twenty-three patients were found to be asthmatic, while three
106 patients were lost to follow-up. Thus, 102 patients were included in the study. The mean age
107 of the patients was 72.9 ± 10.9 years, and 79.4% of the patients were male. Approximately
108 93.1% of the patients had a history of smoking (current or ex-smoker). Both the groups had a
109 severely reduced forced expiratory volume in one second (FEV1) (43.8 ± 17.8 %). In total,
110 42.2% of the patients had eosinophilic AECOPD. Patients with non-eosinophilic AECOPD
111 stayed in the hospital for a longer duration than those with eosinophilic AECOPD ($p = 0.02$).
112 Patients with eosinophilic AECOPD had a significantly higher number of readmissions in a
113 year than those with non-eosinophilic AECOPD ($P = 0.04$). Most patients in both groups
114 received systemic steroids (92.2%) and were on inhaled steroids (78.4%) before admission.
115 There was no significant difference in the need for mechanical ventilation between the groups
116 ($P = 0.32$). Moreover, the eosinophil count before discharge did not differ significantly
117 between the groups ($P = 0.43$).

118

119 **Discussion**

120 The present study is the first to assess the prevalence and clinical significance of eosinophilia
121 in hospitalized COPD patients in the Middle East, where most patients are of Arabic
122 ethnicity. We found that patients with eosinophilic AECOPD have a reduced length of
123 hospital stay but are at an increased risk of readmission in a year.

124

125 The prevalence of eosinophilic AECOPD ranged from 10% to 37% in previous studies.¹³⁻¹⁵
126 These differences in the prevalence of eosinophilia during AECOPD could be explained by
127 the difference in patients' ethnicity, use of corticosteroids before admission, and difference in
128 cut-off values used to define eosinophilia.^{1, 16-18} The most commonly used cut-off value to
129 define eosinophilic COPD is 2%, which corresponds to 150 cells/ μ L. However, the absolute
130 eosinophil count might be more accurate because the white cell count can differ significantly
131 for various reasons.¹ In the present study, we used a cut-off value greater than 300 cells/ μ L to
132 define eosinophilic AECOPD, which has been validated in previous studies.^{1, 7, 16, 19, 20} The
133 prevalence of eosinophilic AECOPD in our cohort was 42.2%, which is higher than most of
134 the previously reported values. This higher prevalence of eosinophilic AECOPD could be

135 related to the high prevalence of smoking in our cohort.

136

137 In patients with COPD and under certain circumstances, the PBEs are recruited to the lungs
138 prompting cascades of inflammatory responses, including secretion of chemokines,
139 cytokines, and cytotoxic granular products.²¹ Most patients in both the groups were treated
140 with inhaled and oral steroids; however, patients with elevated PBE counts showed a better
141 response, as evidenced by a reduced length of hospital stay ($p = 0.02$), which could be
142 explained by the anti-inflammatory role of corticosteroids on patients with eosinophilic
143 AECOPD. Our finding of reduced length of hospital stay of eosinophilic AECOPD is similar
144 to that of previous studies.^{16, 22}

145

146 About 40% of patients with eosinophilic AECOPD required mechanical ventilation compared
147 to 50.9% of patients with non- eosinophilic AECOPD, which may be explained by the poor
148 response of non-eosinophilic AECOPD to corticosteroids. Also, previous studies
149 demonstrated that non-eosinophilic AECOPD is strongly associated with infections and
150 worse outcomes, which may be explained by the higher need for mechanical ventilation.²¹

151

152 There were no significant differences in age, sex, FEV1, and smoking status between the
153 groups (Table 1). In addition, before discharge from the hospital, the eosinophil count did not
154 differ significantly between eosinophilic and non-es eosinophilic AECOPD, which could be
155 explained by a high percentage of patients who were treated with steroids in both groups.

156

157 This finding may provide insight into using oral and inhaled steroids in patients with
158 AECOPD based on the eosinophil count to avoid risks associated with the indiscriminate use
159 of steroids in such patients.²³ There was no difference in the need for mechanical ventilation
160 between the groups ($p = 0.32$). In the present study, the mortality outcome was not assessed
161 because of the small sample size; however, previous studies have suggested that eosinophilic
162 AECOPD is associated with a lower inpatient mortality rate, but the data are conflicting.^{8, 9, 22}

163 In contrast, patients with eosinophilic AECOPD had an increased number of readmissions in
164 a year ($p = 0.04$); this is similar to previous findings.^{17, 22}

165

166 The present study is the first to assess the prevalence of eosinophilia in patients of Arabic
167 ethnicity. The results confirmed that eosinophil count could be used as a surrogate marker to
168 predict the treatment response and risk of readmission in inpatients with AECOPD. This

169 finding supports the 2020 GOLD recommendation regarding the role of PBE in guiding the
170 treatment choice for patients with COPD.¹⁰

171

172 There are several limitations to the present study. First, it was a single-center retrospective
173 study. Second, the inpatient mortality rate in the groups could not be assessed because of the
174 small sample size. Third, the study included hospitalized patients with AECOPD; however, it
175 did not include patients with mild and moderate exacerbations who were managed in the
176 outpatient setting. Moreover, potential cofounders, including heart failure, ischemic heart
177 disease, and hypertension, were not considered.

178

179 **Conclusion**

180 Eosinophilia is highly prevalent in hospitalized patients with AECOPD. It is associated with a
181 reduced length of hospital stay and an increased risk of readmission in a year. In addition, the
182 eosinophil count can be used as a surrogate marker to predict the health outcomes of patients
183 with AECOPD and select treatment options, including corticosteroid use.
